

What is self-discharge in a supercapacitor?

Self-discharge is the loss of capacity caused by a spontaneous drop in voltage when a supercapacitor is left under an open circuit after charging, which is driven by Gibbs free energy [29,30]. The degree of self-discharge also varies for different types of supercapacitors.

Do electrochemical supercapacitors self-discharge?

A study of self-discharge of electrochemical supercapacitors with electrodes based on activated carbon cloth CH 900 (the Kuraray Co. production) and 1 M MgSO_4 aqueous electrolyte is conducted. The rate of self-discharge after ~70 min after its start is found to be proportional to the charging voltage.

How does self-discharge affect the final open-circuit voltage of a supercapacitor?

Eventually, after 5 h of self-discharge, the final open-circuit voltage for the supercapacitor with CNTs was evidently improved (1.18 V) in comparison with the one without CNTs (0.62 V) when the supercapacitors were charged to 1.8 V. Fig. 9.

How can a supercapacitor reduce self-discharge?

The development of new supercapacitor devices destined to minimize the self-discharge is described, including additives to the electrolyte, solid-state supercapacitors, electrochemical supercapacitors with ion-exchange membranes, the using of pure electrolytes, methods of the electrode chemical modification to slow down self-discharge.
